Abstract

We introduce “Talk The Walk”, the first large-scale dialogue dataset grounded in action and perception. The task involves two agents (a “guide” and a “tourist”) that communicate via natural language in order to achieve a common goal: having the tourist navigate to a given target location. The task and dataset, which are described in detail, are challenging and their full solution is an open problem that we pose to the community. We (i) focus on the task of tourist localization and develop the novel Masked Attention for Spatial Convolutions (MASC) mechanism that allows for grounding tourist utterances into the guide’s map, (ii) show it yields significant improvements for both emergent and natural language communication, and (iii) using this method, we establish non-trivial baselines on the full task.

1 Introduction

As artificial intelligence plays an ever more prominent role in everyday human lives, it becomes increasingly important to enable machines to communicate via natural language—not only with humans, but also with each other. Learning algorithms for natural language understanding, such as in machine translation and reading comprehension, have progressed at an unprecedented rate in recent years, but still rely on static, large-scale, text-only datasets that lack crucial aspects of how humans understand and produce natural language. Namely, humans develop language capabilities by being embodied in an environment which they can perceive, manipulate and move around in; and by interacting with other humans. Hence, we argue that we should incorporate all three fundamental aspects of human language acquisition—perception, action and interactive communication—and develop a task and dataset to that effect.

We introduce the Talk the Walk dataset, where the aim is for two agents, a “guide” and a “tourist”, to interact with each other via natural language in order to achieve a common goal: having the tourist navigate towards the correct location. The guide has access to a map and knows the target location, but does not know where the tourist is; the tourist has a 360-degree view of the world, but knows neither the target location on the map nor the way to it. The agents need to work together through communication in order to successfully solve the task. An example of the task is given in Figure 1.

Grounded language learning has (re-)gained traction in the AI community, and much attention is currently devoted to *virtual embodiment*—the development of multi-agent communication tasks in virtual environments—which has been argued to be a viable strategy for acquiring natural language semantics [29]. Various related tasks have recently been introduced, but in each case with some limitations. Although visually grounded dialogue tasks [15, 13] comprise perceptual grounding and multi-agent interaction, their agents are passive observers and do not act in the environment. By contrast, instruction-following tasks, such as VNL [2], involve action and perception but lack natural language interaction with other agents. Furthermore, some of these works use simulated environments [12] and/or templated language [26], which arguably oversimplifies real perception or natural language, respectively. See Table 1 for a comparison.

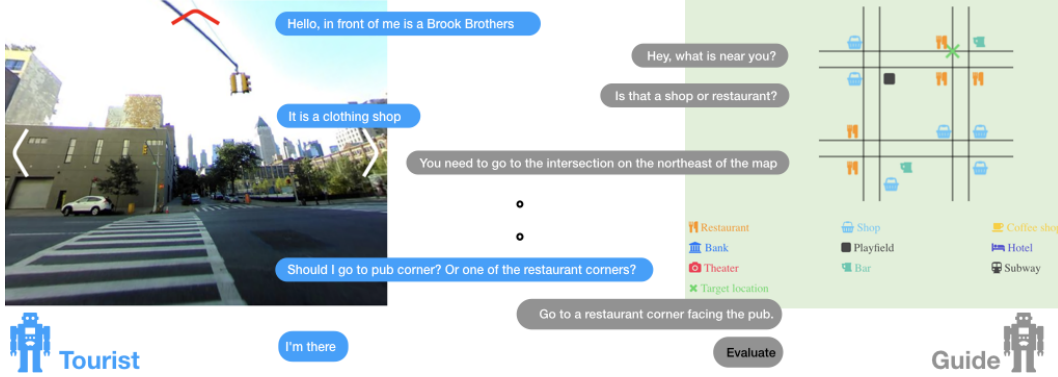

Figure 1: Example of the Talk The Walk task: two agents, a “tourist” and a “guide”, interact with each other via natural language in order to have the tourist navigate towards the correct location. The guide has access to a map and knows the target location but not the tourist location, while the tourist does not know the way but can navigate in a 360-degree street view environment.

Talk The Walk is the first task to bring all three aspects together: *perception* for the tourist observing the world, *action* for the tourist to navigate through the environment, and *interactive dialogue* for the tourist and guide to work towards their common goal. To collect grounded dialogues, we constructed a virtual environment by manually capturing 360 views of several neighborhoods in New York City (NYC)¹. Our street view environment was integrated into ParlAI [38] and used to collect a large-scale dataset on Mechanical Turk involving human perception, action and communication.

We argue that for artificial agents to solve this challenging problem, some fundamental architecture designs are missing, and our hope is that this task motivates their innovation. To that end, we focus on the task of localization and develop the novel Masked Attention for Spatial Convolutions (MASC) mechanism. To model the interaction between language and action, this architecture repeatedly conditions the spatial dimensions of a convolution on the communicated message sequence.

This work makes the following contributions: 1) We present the first large scale dialogue dataset grounded in action and perception; 2) We introduce the MASC architecture for localization and show it yields improvements for both emergent and natural language; 4) Using localization models, we establish initial baselines on the full task; 5) We show that our best model exceeds human performance under the assumption of “perfect perception” and with a learned emergent communication protocol, and sets a non-trivial baseline with natural language.

2 Talk The Walk

We create a perceptual environment by manually capturing several neighborhoods of New York City (NYC) with a 360 camera². Most parts of the city are grid-like and uniform, which makes it well-suited for obtaining a 2D grid. For Talk The Walk, we capture parts of Hell’s Kitchen, East Village, the Financial District, Williamsburg and the Upper East Side—see Figure 5 in Appendix G for their respective locations within NYC. For each neighborhood, we choose an approximately 5x5 grid and capture a 360 view on all four corners of each intersection, leading to a grid-size of roughly 10x10 per neighborhood.

The tourist’s location is given as a tuple (x, y, o) , where x, y are the coordinates and o signifies the orientation (north, east, south or west). The tourist can take three actions: turn left, turn right and go forward. For moving forward, we add $(0, 1)$, $(1, 0)$, $(0, -1)$, $(-1, 0)$ to the x, y coordinates for the respective orientations. Upon a turning action, the orientation is updated by $o = (o + d) \bmod 4$ where $d = -1$ for left and $d = 1$ for right. If the tourist moves outside the grid, we issue a warning that they cannot go in that direction and do not update the location. Moreover, tourists are shown different types of transitions: a short transition for actions that bring the tourist to a different corner of the *same* intersection; and a longer transition for actions that bring them to a new intersection.

¹We avoided using existing street view resources due to licensing issues.

²A 360fly 4K camera.

Project	Perception	Action	Language	Dialogue	Size
Visual Dialog [13]	Real	✗	Human	✓	120k dialogues
GuessWhat [15]	Real	✗	Human	✓	131k dialogues
VNL [2]	Real	✓	Human	✗	23k instructions
Embodied QA [12]	Simulated	✓	Scripted	✗	5k questions
TalkTheWalk	Real	✓	Human	✓	10k dialogues

Table 1: Talk The Walk grounds human generated dialogue in (real-life) perception and action.

The guide observes a map that corresponds to the tourist’s environment. We exploit the fact that urban areas like NYC are full of local businesses, and overlay the map with these landmarks as localization points for our task. Specifically, we manually annotate each corner of the intersection with a set of landmarks $\Lambda^{x,y} = \{l_0, \dots, l_K\}$, each coming from one of the following categories:

- Bar • Bank • Shop • Coffee Shop • Theater
- Playfield • Hotel • Subway • Restaurant

The right-side of Figure 1 illustrates how the map is presented. Note that within-intersection transitions have a smaller grid distance than transitions to new intersections. The coarseness of the landmarks ensures that no single landmark uniquely identifies the location of the tourist. That is, the dialogue is driven by uncertainty in the tourist’s current location and the properties of the target location: if the exact location and orientation of the tourist were known, it would suffice to communicate a sequence of actions.

2.1 Task

For the Talk The Walk task, we randomly choose one of the five neighborhoods, and subsample a 4x4 grid (one block with four complete intersections) from the entire grid. We specify the boundaries of the grid by the top-left and bottom-right corners $(x_{min}, y_{min}, x_{max}, y_{max})$. Next, we construct the overhead map of the environment, i.e. $\{\Lambda^{x',y'}\}$ with $x_{min} \leq x' \leq x_{max}$ and $y_{min} \leq y' \leq y_{max}$. We subsequently sample a start location and orientation (x, y, o) and a target location $(x, y)_{tgt}$ at random³.

The shared goal of the two agents is to navigate the tourist to the target location $(x, y)_{tgt}$, which is only known to the guide. The tourist perceives a “street view” planar projection $S_{x,y,o}$ of the 360 image at location (x, y) and can simultaneously chat with the guide and navigate through the environment. The guide’s role consists of reading the tourist description of the environment, building a “mental map” of their current position and providing instructions for navigating towards the target location. Whenever the guide believes that the tourist has reached the target location, they instruct the system to evaluate the tourist’s location. The task ends when the evaluation is successful—i.e., when $(x, y) = (x, y)_{tgt}$ —or otherwise continues until a total of *three* failed attempts. The additional attempts are meant to ease the task for humans, as we found that they otherwise often fail at the task but still end up close to the target location, e.g., at the wrong corner of the correct intersection.

2.2 Data Collection

We crowd-sourced the collection of the dataset on Amazon Mechanical Turk (MTurk). We use the MTurk interface of ParlAI [38] to render 360 images via WebGL and dynamically display neighborhood maps with an HTML5 canvas. Detailed task instructions, which were also given to our workers before they started their task, are shown in Appendix H. We paired Turkers at random and let them alternate between the tourist and guide role across different HITs. Data was collected over several weeks.

2.3 Dataset Statistics

The Talk The Walk dataset consists of over 10k successful dialogues—see Table 11 in the appendix for the dataset statistics split by neighborhood. More than six hundred Turkers successfully completed at least one Talk The Walk HIT. On average, Turkers needed more than 62 acts (i.e utterances and

³Note that we do not include the orientation in the target, as we found in early experiments that this led to an unnatural task for humans. Similarly, we explored bigger grid sizes but found these to be too difficult for most annotators.

actions) before they successfully complete the task. The majority of acts comprise the tourist’s actions, with on average more than 44 actions per dialogue. The guide produces roughly 9 utterances per dialogue, slightly more than the tourist’s 8 utterances. Turkers use diverse discourse, with a vocabulary size of more than 10K. An example from the dataset is shown in Appendix G.

3 Experiments

The final end-to-end Talk The Walk task is challenging and the full solution is an open problem that we pose to the community. Here, we focus on studying localization, exploring models with emergent and natural language communication, and use localization models to provide baselines for the full task. In order to make headway, in what follows we make the following simplifying assumptions:

Perfect Perception Early experiments revealed that perceptual grounding of landmarks is difficult: we set up a landmark classification problem, on which models with extracted CNN [25] or text recognition features [20] barely outperform a random baseline—see Appendix F for full details. To ensure that perception is not the limiting factor when investigating localization capabilities of models, we assume “perfect perception”: in lieu of the 360 image view, the tourist is given the landmarks at its current location. More formally, each state observation $S^{x,y,o}$ now equals the set of landmarks at the (x, y) -location, i.e. $S^{x,y,o} = \Lambda^{x,y}$. If the (x, y) -location does not have any visible landmarks, we return a single “empty corner” symbol.

Orientation-agnostic tourist We opt to ignore the tourist’s orientation, which simplifies the set of actions to [Left, Right, Up, Down], corresponding to adding $[(-1, 0), (1, 0), (0, 1), (0, -1)]$ to the current (x, y) coordinates, respectively. Note that actions are now coupled to an orientation on the map—e.g. up is equal to going north—and this implicitly assumes that the tourist has access to a compass. This also affects perception, since the tourist now has access to views from all orientations: in conjunction with “perfect perception”, implying that only landmarks at the current corner are given, whereas landmarks from different corners (e.g. across the street) are not visible.

3.1 Tourist Localization

Arguably the most important subtask of Talk The Walk is localization: without being able to localize the tourist, the guide cannot tell if the target location has been reached. Here, we investigate tourist localization with communication in the form of continuous vectors, discrete symbols and natural language.

Emergent language A tourist, starting from a random location, takes $T \geq 0$ *random* actions $A = \{\alpha_0, \dots, \alpha_{T-1}\}$ to reach target location (x_{tgt}, y_{tgt}) . Every location in the environment has a corresponding set of landmarks $\Lambda^{x,y} = \{l_0, \dots, l_K\}$ for each of the (x, y) coordinates. As the tourist navigates, the agent perceives $T + 1$ state-observations $Z = \{\zeta_0, \dots, \zeta_T\}$ where each observation ζ_t consists of a set of K landmark symbols $\{l_0^t, \dots, l_K^t\}$. Given the observations Z and actions A , the tourist generates a message M which is communicated to the other agent. The objective of the guide is to predict the location (x_{tgt}, y_{tgt}) from the tourist’s message M .

Natural language In contrast to our emergent communication experiments, we do not take random actions but instead extract actions, observations, and messages from the dataset. Specifically, we consider each tourist utterance (i.e. at any point in the dialogue), obtain the current tourist location as target location $(x, y)_{tgt}$, the utterance itself as message M , and the sequence of observations and actions that took place between the current and previous tourist utterance as Z and A , respectively. Similar to the emergent language setting, the guide’s objective is to predict the target location $(x, y)_{tgt}$ models from the tourist message M . We conduct experiments with M taken from the dataset and with M generated from the extracted observations Z and actions A .

3.2 Full Task

We establish baselines for the full navigation task by letting trained localization models undertake random walks, using the following protocol: at each step, the tourist communicates its observations to the guide, who predicts the tourist’s location. If the guide predicts that the tourist is at target, we evaluate its location. If successful, the task ends, otherwise we continue until there have been three wrong evaluations. The protocol is given as pseudo-code in Appendix E.

4 Model

We investigate localization, first examining various architectures for the communication channel across which the tourist’s utterances are sent. We subsequently describe how these messages are processed by the guide, and introduce the novel Masked Attention for Spatial Convolutions (MASC) mechanism that allows for grounding tourist utterances into the guide’s map.

4.1 The Tourist

For each of the communication channels, we outline the procedure for generating a message M . Given a set of state observations $\{\zeta_0, \dots, \zeta_T\}$, we represent each observation by summing the L -dimensional embeddings of the observed landmarks, i.e. for $\{\mathbf{o}_0, \dots, \mathbf{o}_T\}$, $\mathbf{o}_t = \sum_{l \in \zeta_t} E^\Lambda(l)$, where E^Λ is the landmark embedding lookup table. In addition, we embed action α_t into a L -dimensional embedding \mathbf{a}_t via a look-up table E^A . We experiment with three types of communication channel.

Continuous vectors The tourist has access to observations of several time steps, whose order is important for accurate localization. Because summing embeddings is order-invariant, we introduce a sum over *positionally-gated* embeddings, which, conditioned on time step t , pushes embedding information into the appropriate dimensions. More specifically, we generate an observation message $\mathbf{m}^{obs} = \sum_{t=0}^T \text{sigmoid}(\mathbf{g}_t) \odot \mathbf{o}_t$, where \mathbf{g}_t is a learned gating vector for time step t . In a similar fashion, we produce action message \mathbf{m}^{act} and send the concatenated vectors $\mathbf{m} = [\mathbf{m}^{obs}; \mathbf{m}^{act}]$ as message to the guide. We can interpret continuous vector communication as a single, monolithic model because its architecture is end-to-end differentiable, enabling gradient-based optimization for training.

Discrete symbols Like the continuous vector communication model, with discrete communication the tourist also uses separate channels for observations and actions, as well as a sum over positionally gated embeddings to generate observation embedding \mathbf{h}^{obs} . We pass this embedding through a sigmoid and generate a message \mathbf{m}^{obs} by sampling from the resulting Bernoulli distributions:

$$\mathbf{h}^{obs} = \sum_{t=0}^T \text{sigmoid}(\mathbf{g}_t) \odot \mathbf{o}_t; \quad \mathbf{m}_i^{obs} \sim \text{Bernoulli}(\text{sigmoid}(h_i^{obs}))$$

The action message \mathbf{m}^{act} is produced in the same way, and we obtain the final tourist message $\mathbf{m} = [\mathbf{m}^{obs}; \mathbf{m}^{act}]$ through concatenating the messages.

The communication channel’s sampling operation yields the model non-differentiable, so we use policy gradients [47, 48] to train the parameters θ of the tourist model. That is, we estimate the gradient by

$$\nabla_\theta E_{\mathbf{m} \sim p(\mathbf{h})}[r(\mathbf{m})] = E_{\mathbf{m}}[\nabla_\theta \log p(\mathbf{m})(r(\mathbf{m}) - b)],$$

where the reward function $r(\mathbf{m}) = -\log p(x, y)_{tgt} | \mathbf{m}, \Lambda$ is the negative guide’s loss (see Section 4.2) and b a state-value baseline to reduce variance. We use a linear transformation over the concatenated embeddings as baseline prediction, i.e. $b = W^{base}[\mathbf{h}^{obs}; \mathbf{h}^{act}] + \mathbf{b}^{base}$, and train it with a mean squared error loss⁴.

Natural Language Because observations and actions are of variable-length, we use an LSTM encoder over the sequence of observations embeddings $[\mathbf{o}_t]_{t=0}^{T+1}$, and extract its last hidden state \mathbf{h}^{obs} . We use a separate LSTM encoder for action embeddings $[\mathbf{a}_t]_{t=0}^T$, and concatenate both \mathbf{h}^{obs} and \mathbf{h}^{act} to the input of the LSTM decoder at each time step:

$$\begin{aligned} \mathbf{i}_k &= [E^{dec}(w_{k-1}); \mathbf{h}^{obs}; \mathbf{h}^{act}] & \mathbf{h}_k^{dec} &= f_{LSTM}(\mathbf{i}_k, \mathbf{h}_{k-1}^{dec}) \\ p(w_k | w_{<k}, A, Z) &= \text{softmax}(W^{out} \mathbf{h}_k^{dec} + \mathbf{b}^{out})_k, \end{aligned} \quad (1)$$

where E^{dec} a look-up table, taking input tokens w_k . We train with teacher-forcing, i.e. we optimize the cross-entropy loss: $-\sum_K \log p(w_k | w_{<k}, A, Z)$. At test time, we explore the following decoding strategies: greedy, sampling and a beam-search. We also fine-tune a trained tourist model (starting from a pre-trained model) with policy gradients in order to minimize the guide’s prediction loss.

⁴This is different from A2C which uses a state-value baseline that is trained by the Bellman residual

4.2 The Guide

Given a tourist message M describing their observations and actions, the objective of the guide is to predict the tourist’s location on the map. First, we outline the procedure for extracting observation embedding \mathbf{e} and action embeddings \mathbf{a}_t from the message M for each of the types of communication. Next, we discuss the MASC mechanism that takes the observations and actions in order to ground them on the guide’s map in order to predict the tourist’s location.

Continuous For the continuous communication model, we assign the observation message to the observation embedding, i.e. $\mathbf{e} = \mathbf{m}^{obs}$. To extract the action embedding for time step t , we apply a linear layer to the action message, i.e. $\mathbf{a}_t = W_t^{act} \mathbf{m}^{act} + \mathbf{b}_t^{act}$.

Discrete For discrete communication, we obtain observation \mathbf{e} by applying a linear layer to the observation message, i.e. $\mathbf{e} = W^{obs} \mathbf{m}^{obs} + \mathbf{b}^{obs}$. Similar to the continuous communication model, we use a linear layer over action message \mathbf{m}^{act} to obtain action embedding \mathbf{a}_t for time step t .

Natural Language The message M contains information about observations and actions, so we use a recurrent neural network with attention mechanism to extract the relevant observation and action embeddings. Specifically, we encode the message M , consisting of K tokens w_k taken from vocabulary V , with a bidirectional LSTM:

$$\vec{\mathbf{h}}_k = f_{LSTM}(\vec{\mathbf{h}}_{k-1}, E^W(w_k)); \quad \overleftarrow{\mathbf{h}}_k = f_{LSTM}(\overleftarrow{\mathbf{h}}_{k+1}, E^W(w_k)); \quad \mathbf{h}_k = [\vec{\mathbf{h}}_k; \overleftarrow{\mathbf{h}}_k] \quad (2)$$

where E^W is the word embedding look-up table. We obtain observation embedding \mathbf{e}_t through an attention mechanism over the hidden states \mathbf{h} :

$$s_k = \mathbf{h}_k \cdot \mathbf{c}_t; \quad \mathbf{e}_t = \sum_k \text{softmax}(s) \mathbf{h}_k, \quad (3)$$

where \mathbf{c}_0 is a learned control embedding who is updated through a linear transformation of the previous control and observation embedding: $\mathbf{c}_{t+1} = W^{ctrl}[\mathbf{c}_t; \mathbf{e}_t] + \mathbf{b}^{ctrl}$. We use the same mechanism to extract the action embedding \mathbf{a}_t from the hidden states. For the observation embedding, we obtain the final representation by summing positionally gated embeddings, i.e., $\mathbf{e} = \sum_{t=0}^T \text{sigmoid}(\mathbf{g}_t) \odot \mathbf{e}_t$.

4.2.1 Masked Attention for Spatial Convolutions (MASC)

We represent the guide’s map as $U \in \mathbb{R}^{G_1 \times G_2 \times L}$, where in this case $G_1 = G_2 = 4$, where each L -dimensional (x, y) location embedding $\mathbf{u}^{x,y}$ is computed as the sum of the guide’s landmark embeddings for that location.

Motivation While the guide’s map representation contains only local landmark information, the tourist communicates a trajectory of the map (i.e. actions and observations from multiple locations), implying that directly comparing the tourist’s message with the individual landmark embeddings is probably suboptimal. Instead, we want to aggregate landmark information from surrounding locations by imputing trajectories over the map to predict locations. We propose a mechanism for translating landmark embeddings according to state transitions (left, right, up, down), which can be expressed as a 2D convolution over the map embeddings. For simplicity, let us assume that the map embedding U is 1-dimensional, then a left action can be realized through application of the following 3×3 kernel: $\begin{bmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$, which effectively shifts all values of U one position to the left. We propose to learn such state-transitions from the tourist message through a differentiable attention-mask over the spatial dimensions of a 3×3 convolution.

MASC We linearly project each predicted action embedding \mathbf{a}_t to a 9-dimensional vector \mathbf{z}_t , normalize it by a softmax and subsequently reshape the vector into a 3×3 mask Φ_t :

$$\mathbf{z}_t = W^{act} \mathbf{a}_t + \mathbf{b}^{act}, \quad \phi_t = \text{softmax}(\mathbf{z}_t), \quad \Phi_t = \begin{bmatrix} \phi_t^0 & \phi_t^1 & \phi_t^2 \\ \phi_t^3 & \phi_t^4 & \phi_t^5 \\ \phi_t^6 & \phi_t^7 & \phi_t^8 \end{bmatrix}. \quad (4)$$

We learn a 3×3 convolutional kernel $W \in \mathbb{R}^{3 \times 3 \times N \times N}$, with N features, and apply the mask Φ_t to the spatial dimensions of the convolution by first broadcasting its values along the feature dimensions, i.e. $\hat{\Phi}^{x,y,i,j} = \Phi^{x,y}$, and subsequently taking the Hadamard product: $W_t = \hat{\Phi}_t \odot W$. For each action step t , we then apply a 2D convolution with masked weight W_t to obtain a new map embedding $U_{t+1} = U_t * W_t$, where we zero-pad the input to maintain identical spatial dimensions.

	MASC	Cont.	Train Disc.	Upper	Cont.	Valid Disc.	Upper	Cont.	Test Disc.	Upper

	✓	71.32	71.80	87.92	67.48	65.63	87.45	69.85	69.51	92.41

Table 2: Accuracy results for tourist localization with emergent language, showing continuous (Cont.) and discrete (Disc.) communication, along with the prediction upper bound. T denotes the length of the path and a ✓ in the “MASC” column indicates that the model is conditioned on the communicated actions.

Prediction model We repeat the MASC operation T times (i.e. once for each action), and then aggregate the map embeddings by a sum over positionally-gated embeddings: $\mathbf{u}^{x,y} = \sum_{t=0}^T \text{sigmoid}(\mathbf{g}_t) \odot \mathbf{u}_t^{x,y}$. We score locations by taking the dot-product of the observation embedding \mathbf{e} , which contains information about the sequence of observed landmarks by the tourist, and the map. We compute a distribution over the locations of the map $p(x, y|M, \Lambda)$ by taking a softmax over the computed scores:

$$s^{x,y} = \mathbf{e} \cdot \mathbf{u}^{x,y}, \quad p(x, y|M, \Lambda) = \frac{\exp(s^{x,y})}{\sum_{x',y'} \exp(s^{x',y'})}. \quad (5)$$

Predicting T While emergent communication models use a fixed length trajectory T , natural language messages may differ in the number of communicated observations and actions. Hence, we predict T from the communicated message. Specifically, we use a softmax regression layer over the last hidden state \mathbf{h}_K of the RNN, and subsequently sample T from the resulting multinomial distribution:

$$\mathbf{z} = \text{softmax}(W^{tm}\mathbf{h}_K + \mathbf{b}^{tm}); \quad \hat{T} \sim \text{Multinomial}(\mathbf{z}). \quad (6)$$

We jointly train the T -prediction model via REINFORCE, with the guide’s loss as reward function and a mean-reward baseline.

4.3 Comparisons

To better analyze the performance of the models incorporating MASC, we compare against a no-MASC baseline in our experiments, as well as a prediction upper bound.

No MASC We compare the proposed MASC model with a model that does not include this mechanism. Whereas MASC predicts a convolution mask from the tourist message, the “No MASC” model uses W , the ordinary convolutional kernel to convolve the map embedding U_t to obtain U_{t+1} . We also share the weights of this convolution at each time step.

Prediction upper-bound Because we have access to the class-conditional likelihood $p(Z, A|x, y)$, we are able to compute the Bayes error rate (or irreducible error). No model (no matter how expressive) with any amount of data can ever do better than this accuracy as there are multiple observations consistent with the labels.

5 Results and Discussion

We first report the results for tourist localization with **emergent language** in Table 2.

Task is not too easy The upper-bound on localization performance suggest that communicating a single landmark observation is not sufficient for accurate localization of the tourist ($\sim 35\%$ accuracy). This is an important result because the need for two-way communication disappears if localization is too easy; if the guide knows the exact location of the tourist it suffices to communicate a list of

Model	Decoding	Train	Valid	Test		Train	Valid	Test	#steps

Table 3: **Localization** accuracy of tourist communicating in natural language.

Table 4: **Full task** evaluation of localization models using protocol of Appendix E.

instructions, which is then executed by the tourist. The uncertainty in the tourist’s location is what drives the dialogue between the two agents.

Importance of actions We observe that the upperbound for only communicating observations plateaus around 57%, whereas it exceeds 90% when we also take actions into account. This implies that, at least for random walks, it is essential to communicate the tourist’s actions in order to achieve high localization accuracy.

MASC improves performance The MASC architecture significantly improves performance compared to models that do not include this mechanism. For instance, for $T = 1$ MASC already achieves 56.09 % on the test set and this further increases to 69.85% for $T = 3$ actions. On the other hand, no-MASC models hit a plateau at 43%. In Appendix D, we analyze learned MASC values, and show that communicated actions are often mapped to corresponding state-transitions.

Continuous vs discrete We observe similar performance for continuous and discrete emergent communication models, implying that a discrete communication channel is not a limiting factor for localization performance.

We report the results of tourist localization with **natural language** in Table 3. We compare accuracy of the guide model (with MASC) trained on (i) human utterances, (ii) a supervised model with various decoding strategies, and (iii) a policy gradient model optimized with respect to the loss of a frozen, pre-trained guide model on *human* utterances.

Generated utterances are more informative Interestingly, we observe that the supervised model (with greedy and beam-search decoding) as well as the policy gradient model significantly outperforms human generated utterances in terms of localization accuracy. We analyze samples of these models in Appendix D, and show that, unlike human utterances, the generated utterances are talking about the observed landmarks. Hence, the tourist models learn to denoise the training signal via grounding, conditioning the language decoder on the encoded actions and observations.

Humans are bad localizers The fact that (i) our best emergent communication model is much stronger (achieving almost 70%) than our best localization model from human utterances (around 20%, see Appendix D) and (ii) that generated utterances are more informative for localization than human utterances, suggests that humans are bad localizers because they do not always communicate their observations and actions well.

Table 4 shows results for localization models on the **full task**.

Exceeding human performance Interestingly, our best localization model (continuous communication, with MASC, and $T = 3$) achieves 88.33% on the test set and thus exceed human performance of 76.74% on the full task. While emergent models appear to be stronger localizers, humans might cope with their localization uncertainty through other mechanisms (e.g. better guidance, bias towards taking particular paths, etc). The simplifying assumption of perfect perception likely also helps.

Number of actions Unsurprisingly, humans take fewer steps (roughly 15) than our best random walk model (roughly 34). Our human annotators likely used some form of guidance to navigate faster to the target. This gap is a challenge that should motivate developing more sophisticated models.

6 Conclusion

We introduced the Talk The Walk task and dataset, which consists of crowd-sourced dialogues in which two human annotators collaborate to navigate to target locations in the virtual streets of NYC. For the important localization sub-task, we proposed MASC—a novel grounding mechanism to learn state-transition from the tourist’s message—and showed that it improves localization performance for emergent and natural language. We believe Talk The Walk is a useful resource for grounded language learning, and hope it will facilitate research on the intersection of computer vision, goal-directed dialogue systems, reinforcement learning, navigation, and planning.

Acknowledgement We thank Jack Urbanek and Will Feng for their help on integrating Talk The Walk into ParlAI, and Saizheng Zhang, Florian Strub, and Ethan Perez for their comments on an early draft of this paper.

A Related Work

The Talk the Walk task and dataset facilitate future research on various important subfields of artificial intelligence, including grounded language learning, goal-oriented dialogue research and situated navigation. Here, we describe related previous work in these areas.

Related tasks There has been a long line of work involving related tasks. Early work on task-oriented dialogue dates back to the early 90s with the introduction of the Map Task [1] and Maze Game [19] corpora. Recent efforts have led to larger-scale goal-oriented dialogue datasets, for instance to aid research on visually-grounded dialogue [13, 15], knowledge-base-grounded discourse [24] or negotiation tasks [34]. At the same time, there has been a big push to develop environments for embodied AI, many of which involve agents following natural language instructions with respect to an environment [4, 50, 26, 37, 10, 9], following-up on early work in this area [36, 11]. An early example of navigation using neural networks is [23], who propose an online learning approach for robot navigation. Recently, there has been increased interest in using end-to-end trainable neural networks for learning to navigate indoor scenes [22, 21] or large cities [8, 39], but, unlike our work, without multi-agent communication. Also the task of localization (without multi-agent communication) has recently been studied in [9].

Grounded language learning Grounded language learning is motivated by the observation that humans learn language embodied (grounded) in sensorimotor experience of the physical world [6, 44]. On the one hand, work in multi-modal semantics has shown that grounding can lead to practical improvements on various natural language understanding tasks [see 5, 28, and references therein]. In robotics, researchers dissatisfied with purely symbolic accounts of meaning attempted to build robotic systems with the aim of grounding meaning in physical experience of the world [43, 45]. Recently, grounding has also been applied to the learning of sentence representations [30], image captioning [35, 49], visual question answering [3, 16], visual reasoning [27, 41], and grounded machine translation [42, 17]. Grounding also plays a crucial role in the emergent research of multi-agent communication, where, agents communicate (in natural language or otherwise) in order to solve a task, with respect to their shared environment [33, 14, 40, 18, 34, 46, 32].

B Implementation Details

For the emergent communication models, we use an embedding size $L = 500$. The natural language experiments use 128-dimensional word embeddings and a bidirectional RNN with 256 units. In all experiments, we train the guide with a cross entropy loss using the ADAM optimizer with default hyper-parameters [31]. We perform early stopping on the validation accuracy, and report the corresponding train, valid and test accuracy. We optimize the localization models with continuous, discrete and natural language communication channels for 200, 200, and 25 epochs, respectively. To facilitate further research on Talk The Walk, we make our code base for reproducing experiments publicly available at <https://github.com/facebookresearch/talkthewalk>.

C Additional Experiments

First, we investigate localization performance of MASC and no-MASC models for increasing dialogue context. Next, using beam-search decoding for generating a single tourist utterance, we show that localization accuracy deteriorates for increasing beam-size. Lastly, we compare full task performance of natural language models trained on human and random walk trajectories, finding that best performance is attained for random walks with $T = 0$, i.e. for models conditioned on a single observation.

Localization improves with more dialogue context We conduct an ablation study for MASC on natural language with varying dialogue context. Specifically, we compare localization accuracy of MASC and no-MASC models trained on the last [1, 3, 5] utterances of the dialogue (including guide utterances). We report these results in Table 5. In all cases, MASC outperforms the no-MASC models by several accuracy points. We also observe that mean predicted \hat{T} (over the test set) increases from 1 to 2 when more dialogue context is included.

Increasing beam size lowers performance We report localization performance of tourist utterances generated by beam search decoding of *varying beam size* in Table 6. We find that performance decreases from 29.05% to 20.87% accuracy on the test set when we increase the beam-size from one to eight.

#utterances	MASC	Train	Valid	Test	$E[T]$
Random		6.25	6.25	6.25	-
1	✗	23.95	13.91	13.89	0.99
	✓	23.46	15.56	16.17	1.00
3	✗	26.92	16.28	16.62	1.00
	✓	20.88	17.50	18.80	1.79
5	✗	25.75	16.11	16.88	1.98
	✓	30.45	18.41	20.33	1.99

Table 5: Localization given last $\{1, 3, 5\}$ dialogue utterances (including the guide). We observe that 1) performance increases when more utterances are included; and 2) MASC outperforms no-MASC in all cases; and 3) mean \hat{T} increases when more dialogue context is included.

Beam size	Train	Valid	Test
Random	6.25	6.25	6.25
1	34.14	29.90	29.05
2	26.24	23.65	25.10
4	23.59	22.87	21.80
8	20.31	19.24	20.87

Table 6: Localization performance using pre-trained tourist (via imitation learning) with beam search decoding of varying beam size. We find that larger beam-sizes lead to worse localization performance.

Trajectories	T	Train	Valid	Test
Random		18.75	18.75	18.75
Human	0	38.21	40.93	40.00
	1	21.82	23.75	25.62
	2	19.77	24.68	23.12
	3	18.95	20.93	20.00
All	0	39.65	39.68	50.00
	1	28.99	30.93	25.62
	2	27.04	19.06	19.38
	3	20.28	20.93	22.50

Table 7: Full task performance of localization models trained on human and random trajectories. There are small benefits for training on random trajectories, but the most important hyperparameter is to condition the tourist utterance on a single observation (i.e. trajectories of size $T = 0$.)

Human vs random trajectories So far, all natural language experiments have been conducted on human trajectories (taken from the dataset). However, during full task evaluation the tourist undertakes a random walk which is probably very different from human trajectories. To investigate the impact of different train and test trajectories, we also train agents to perform localization on random trajectories. Specifically, we use a pre-trained tourist model with greedy decoding, and train a guide model on random trajectories of varying length T . After optimization, we evaluate the trained tourist and guide on the full task, and compare performance to models trained on human trajectories. Table 7 shows the results. We observe small improvements for training on random trajectories over human trajectories. However, by far the most important factor for strong performance is to use short trajectories of size $T = 0$, i.e. to condition the tourist model on a single observation.

D Additional Analysis

In this section, we provide additional analysis of the trained MASC models. First, we visualize the learned MASC values for one of the emergent communication models. Next, we analyze samples of tourist models communicating in natural language.

Visualizing MASC predictions Figure 2 shows the MASC values for a learned model with emergent discrete communications and $T = 3$ actions. Specifically, we look at the predicted MASC values for different action sequences taken by the tourist. We observe that the first action is always mapped to the correct state-transition, but that the second and third MASC values do not always correspond to right state-transitions.

Method	Decoding	Utterance
Observations		(Bar)
Actions		-
Human		a field of some type
Supervised	greedy sampling beam search	at a bar sec just hard to tell which is a restaurant ? im at a bar
Policy Grad.	greedy sampling	bar from bar from bar and rigth rigth bulding bulding which bar from bar from bar and bar rigth bulding bulding..

Table 8: Samples from the tourist models communicating in natural language.

Analyzing tourist samples Table 8 shows samples of the trained tourist models, illustrating the differences between them. First, we observe that the ground-truth human utterance and vanilla sampling of the supervised model does not always ground the message into the observations. For example, the human utterance does not mention the bar, neither does the vanilla sample (which mentions a restaurant). By contrast, greedy and beam-search decoding both produce samples that mention that they are at the bar (the observed landmark). Also the policy gradient model mentions the observed landmark, but the generated sample has lost some linguistic structure.

Figure 2: We show MASC values of two action sequences for tourist localization via *discrete* communication with $T = 3$ actions. In general, we observe that the first action always corresponds to the correct state-transition, whereas the second and third are sometimes mixed. For instance, in the top example, the first two actions are correctly predicted but the third action is not (as the MASC corresponds to a “no action”). In the bottom example, the second action appears as the third MASC.

E Evaluation on Full Setup

We provide pseudo-code for evaluation of localization models on the full task in Algorithm 1, as well as results for all emergent communication models in Table 9.

T	MASC	Comm.	Train	Valid	Test	#steps

F Landmark Classification

While the guide has access to the landmark labels, the tourist needs to recognize these landmarks from raw perceptual information. In this section, we study landmark classification as a supervised learning problem to investigate the difficulty of perceptual grounding in Talk The Walk.

The Talk The Walk dataset contains a total of 307 different landmarks divided among nine classes, see Figure 4 for how they are distributed. The class distribution is fairly imbalanced, with shops and restaurants as the most frequent landmarks and relatively few play fields and theaters. We treat landmark recognition as a multi-label classification problem as there can be multiple landmarks on a corner⁵.

For the task of landmark classification, we extract the relevant views of the 360 image from which a landmark is visible. Because landmarks are labeled to be on a specific corner of an intersection, we assume that they are visible from one of the orientations facing away from the intersection. For example, for a landmark on the northwest corner of an intersection, we extract views from both

⁵Strictly speaking, this is more general than a multi-label setup because a corner might contain multiple landmarks of the same class.

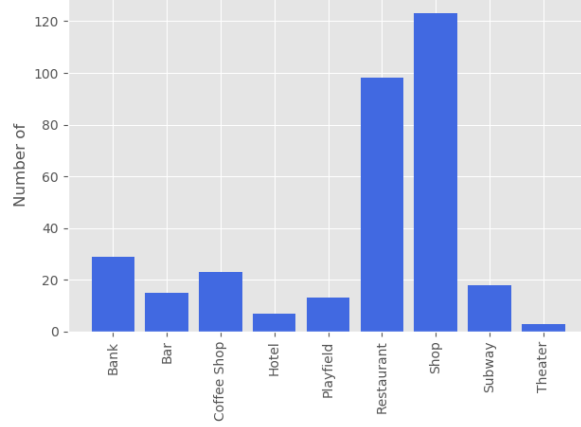

Figure 4: Frequency of landmark classes

Features	Train loss	Valid Loss	Train F1	Valid F1	Valid prec.	Valid recall
All positive	-	-	-	0.39313	0.26128	1
Random (0.5)	-	-	-	0.32013	0.24132	0.25773

ResNet	0.00735	0.00751	0.17085	0.20159	0.13114	0.58763
ResNet (256 dim)	0.0051	0.00748	0.60911	0.31953	0.27733	0.50515

Table 10: Results for **landmark classification**.

the north and west direction. The orientation-specific views are obtained by a planar projection of the full 360-image with a small field of view (60 degrees) to limit distortions. To cover the full field of view, we extract two images per orientation, with their horizontal focus point 30 degrees apart. Hence, we obtain eight images per 360 image with corresponding orientation $v \in \{N1, N2, E1, E2, S1, S2, W1, W2\}$.

We run the following pre-trained feature extractors over the extracted images:

ResNet We resize the extracted view to a 224x224 image and pass it through a ResNet-152 network [25] to obtain a 2048-dimensional feature vector $S_{x,y,v}^{resnet} \in \mathbb{R}^{2048}$ from the penultimate layer.

Text Recognition We use a pre-trained text-recognition model [20] to extract a set of text messages $S_{x,y,v}^{text} = \{R_{\beta}^{text}\}_{\beta=0}^B$ from the images. Local businesses often advertise their wares through key phrases on their storefront, and understanding this text might be a good indicator of the type of landmark. In Figure 3, we show the results of running the text recognition module on a few extracted images.

For the text recognition model, we use a learned look-up table E^{text} to embed the extracted text features $\mathbf{e}_{x,y,v}^{\beta} = E^{text}(R_{\beta}^{text})$, and fuse all embeddings of four images through a bag of embeddings, i.e., $\mathbf{e}^{fused} = \sum_{v \in \text{relevant views}} \sum_{\beta} e_{x,y,v}^{\beta}$. We use a linear layer followed by a sigmoid to predict the probability for each class, i.e. $\text{sigmoid}(W\mathbf{e}^{fused} + b)$. We also experiment with replacing the look-up embeddings with pre-trained FastText embeddings [7]. For the ResNet model, we use a bag of embeddings over the four ResNet features, i.e. $\mathbf{e}^{fused} = \sum_{v \in \text{relevant views}} S_{x,y,v}^{resnet}$, before we pass it through a linear layer to predict the class probabilities: $\text{sigmoid}(W\mathbf{e}^{fused} + b)$. We also conduct experiments where we first apply PCA to the extracted ResNet and FastText features before we feed them to the model.

To account for class imbalance, we train all described models with a binary cross entropy loss weighted by the inverted class frequency. We create a 80-20 class-conditional split of the dataset into a training and validation set. We train for 100 epochs and perform early stopping on the validation loss.

The F1 scores for the described methods in Table 10. We compare to an “all positive” baseline that always predicts that the landmark class is visible and observe that all presented models struggle to outperform this baseline. Although 256-dimensional ResNet features achieve slightly better precision on the validation set, it results in much worse recall and a lower F1 score. Our results indicate that perceptual grounding is a difficult task, which easily merits a paper of its own right, and so we leave further improvements (e.g. better text recognizers) for future work.

G Dataset Details

Figure 5: Map of New York City with red rectangles indicating the captured neighborhoods of the Talk The Walk dataset.

Neighborhood	#success	#failed	#disconnects
Hell’s Kitchen	2075	762	867
Williamsburg	2077	683	780
East Village	2035	713	624
Financial District	2042	607	497
Upper East	2081	359	576
Total	10310	3124	3344

Table 11: Dataset statistics split by neighborhood and dialogue status.

Dataset split We split the full dataset by assigning entire 4x4 grids (independent of the target location) to the train, valid or test set. Specifically, we design the split such that the valid set contains at least one intersection (out of four) is not part of the train set. For the test set, all four intersections are novel. See our source code, available at <https://github.com/facebookresearch/talkthewalk>, for more details on how this split is realized.

Example

```
Tourist: ACTION:TURNRIGHT ACTION:TURNRIGHT
Guide: Hello, what are you near?
Tourist: ACTION:TURNLEFT ACTION:TURNLEFT ACTION:TURNLEFT
Tourist: Hello, in front of me is a Brooks Brothers
Tourist: ACTION:TURNLEFT ACTION:FORWARD ACTION:TURNLEFT ACTION:TURNLEFT
Guide: Is that a shop or restaurant?
Tourist: ACTION:TURNLEFT
Tourist: It is a clothing shop.
Tourist: ACTION:TURNLEFT
Guide: You need to go to the intersection in the northwest corner of the map
Tourist: ACTION:TURNLEFT
Tourist: There appears to be a bank behind me.
Tourist: ACTION:TURNLEFT ACTION:TURNLEFT ACTION:TURNRIGHT ACTION:TURNRIGHT
Guide: Ok, turn left then go straight up that road
Tourist: ACTION:TURNLEFT ACTION:TURNLEFT ACTION:TURNLEFT ACTION:FORWARD ACTION:TURNRIGHT
ACTION:FORWARD ACTION:FORWARD ACTION:TURNLEFT ACTION:TURNLEFT ACTION:TURNLEFT
Guide: There should be shops on two of the corners but you
need to go to the corner without a shop.
Tourist: ACTION:FORWARD ACTION:FORWARD ACTION:FORWARD ACTION:TURNLEFT ACTION:TURNLEFT
Guide: let me know when you get there.
Tourist: on my left is Radio city Music hall
```

Tourist: ACTION:TURNLEFT ACTION:FORWARD ACTION:TURNLEFT ACTION:TURNRIGHT ACTION:TURNRIGHT
 Tourist: I can't go straight any further.
 Guide: ok. turn so that the theater is on your right.
 Guide: then go straight
 Tourist: That would be going back the way I came
 Guide: yeah. I was looking at the wrong bank
 Tourist: I'll notify when I am back at the brooks brothers, and the bank.
 Tourist: ACTION:TURNRIGHT
 Guide: make a right when the bank is on your left
 Tourist: ACTION:FORWARD ACTION:FORWARD ACTION:TURNRIGHT
 Tourist: Making the right at the bank.
 Tourist: ACTION:FORWARD ACTION:FORWARD
 Tourist: I can't go that way.
 Tourist: ACTION:TURNLEFT
 Tourist: Bank is ahead of me on the right
 Tourist: ACTION:FORWARD ACTION:FORWARD ACTION:TURNLEFT
 Guide: turn around on that intersection
 Tourist: I can only go to the left or back the way I just came.
 Tourist: ACTION:TURNLEFT
 Guide: you're in the right place. do you see shops on the corners?
 Guide: If you're on the corner with the bank, cross the street
 Tourist: I'm back where I started by the shop and the bank.
 Tourist: ACTION:TURNRIGHT
 Guide: on the same side of the street?
 Tourist: crossing the street now
 Tourist: ACTION:FORWARD ACTION:FORWARD ACTION:TURNLEFT
 Tourist: there is an I love new york shop across the street on the left from me now
 Tourist: ACTION:TURNRIGHT ACTION:FORWARD
 Guide: ok. I'll see if it's right.
 Guide: EVALUATE_LOCATION
 Guide: It's not right.
 Tourist: What should I be on the look for?
 Tourist: ACTION:TURNRIGHT ACTION:TURNRIGHT ACTION:TURNRIGHT
 Guide: There should be shops on two corners but you need to be on one of the corners
 without the shop.
 Guide: Try the other corner.
 Tourist: this intersection has 2 shop corners and a bank corner
 Guide: yes. that's what I see on the map.
 Tourist: should I go to the bank corner? or one of the shop corners?
 or the blank corner (perhaps a hotel)
 Tourist: ACTION:TURNLEFT ACTION:TURNLEFT ACTION:TURNRIGHT ACTION:TURNRIGHT
 Guide: Go to the one near the hotel. The map says the hotel is a little
 further down but it might be a little off.
 Tourist: It's a big hotel it's possible.
 Tourist: ACTION:FORWARD ACTION:TURNLEFT ACTION:FORWARD ACTION:TURNRIGHT
 Tourist: I'm on the hotel corner
